ASSESSING POST-WILDFIRE REGENERATION

NON-DESTRUCTIVE CONIFER SEEDLING AGING

DARCY HAMMOND AND EVA STRAND

POST-FIRE REGENERATION

- I** Measuring post-fire conifer establishment date and growth is an important part of monitoring ecosystem recovery and trajectory following fires

SEEDLING AGING METHODS

- I** Most methods are destructive
 - Counting rings
 - Coring
- I** Accuracy is generally better with destructive methods but not perfect
- I** Non-destructive methods are generally faster and require less processing

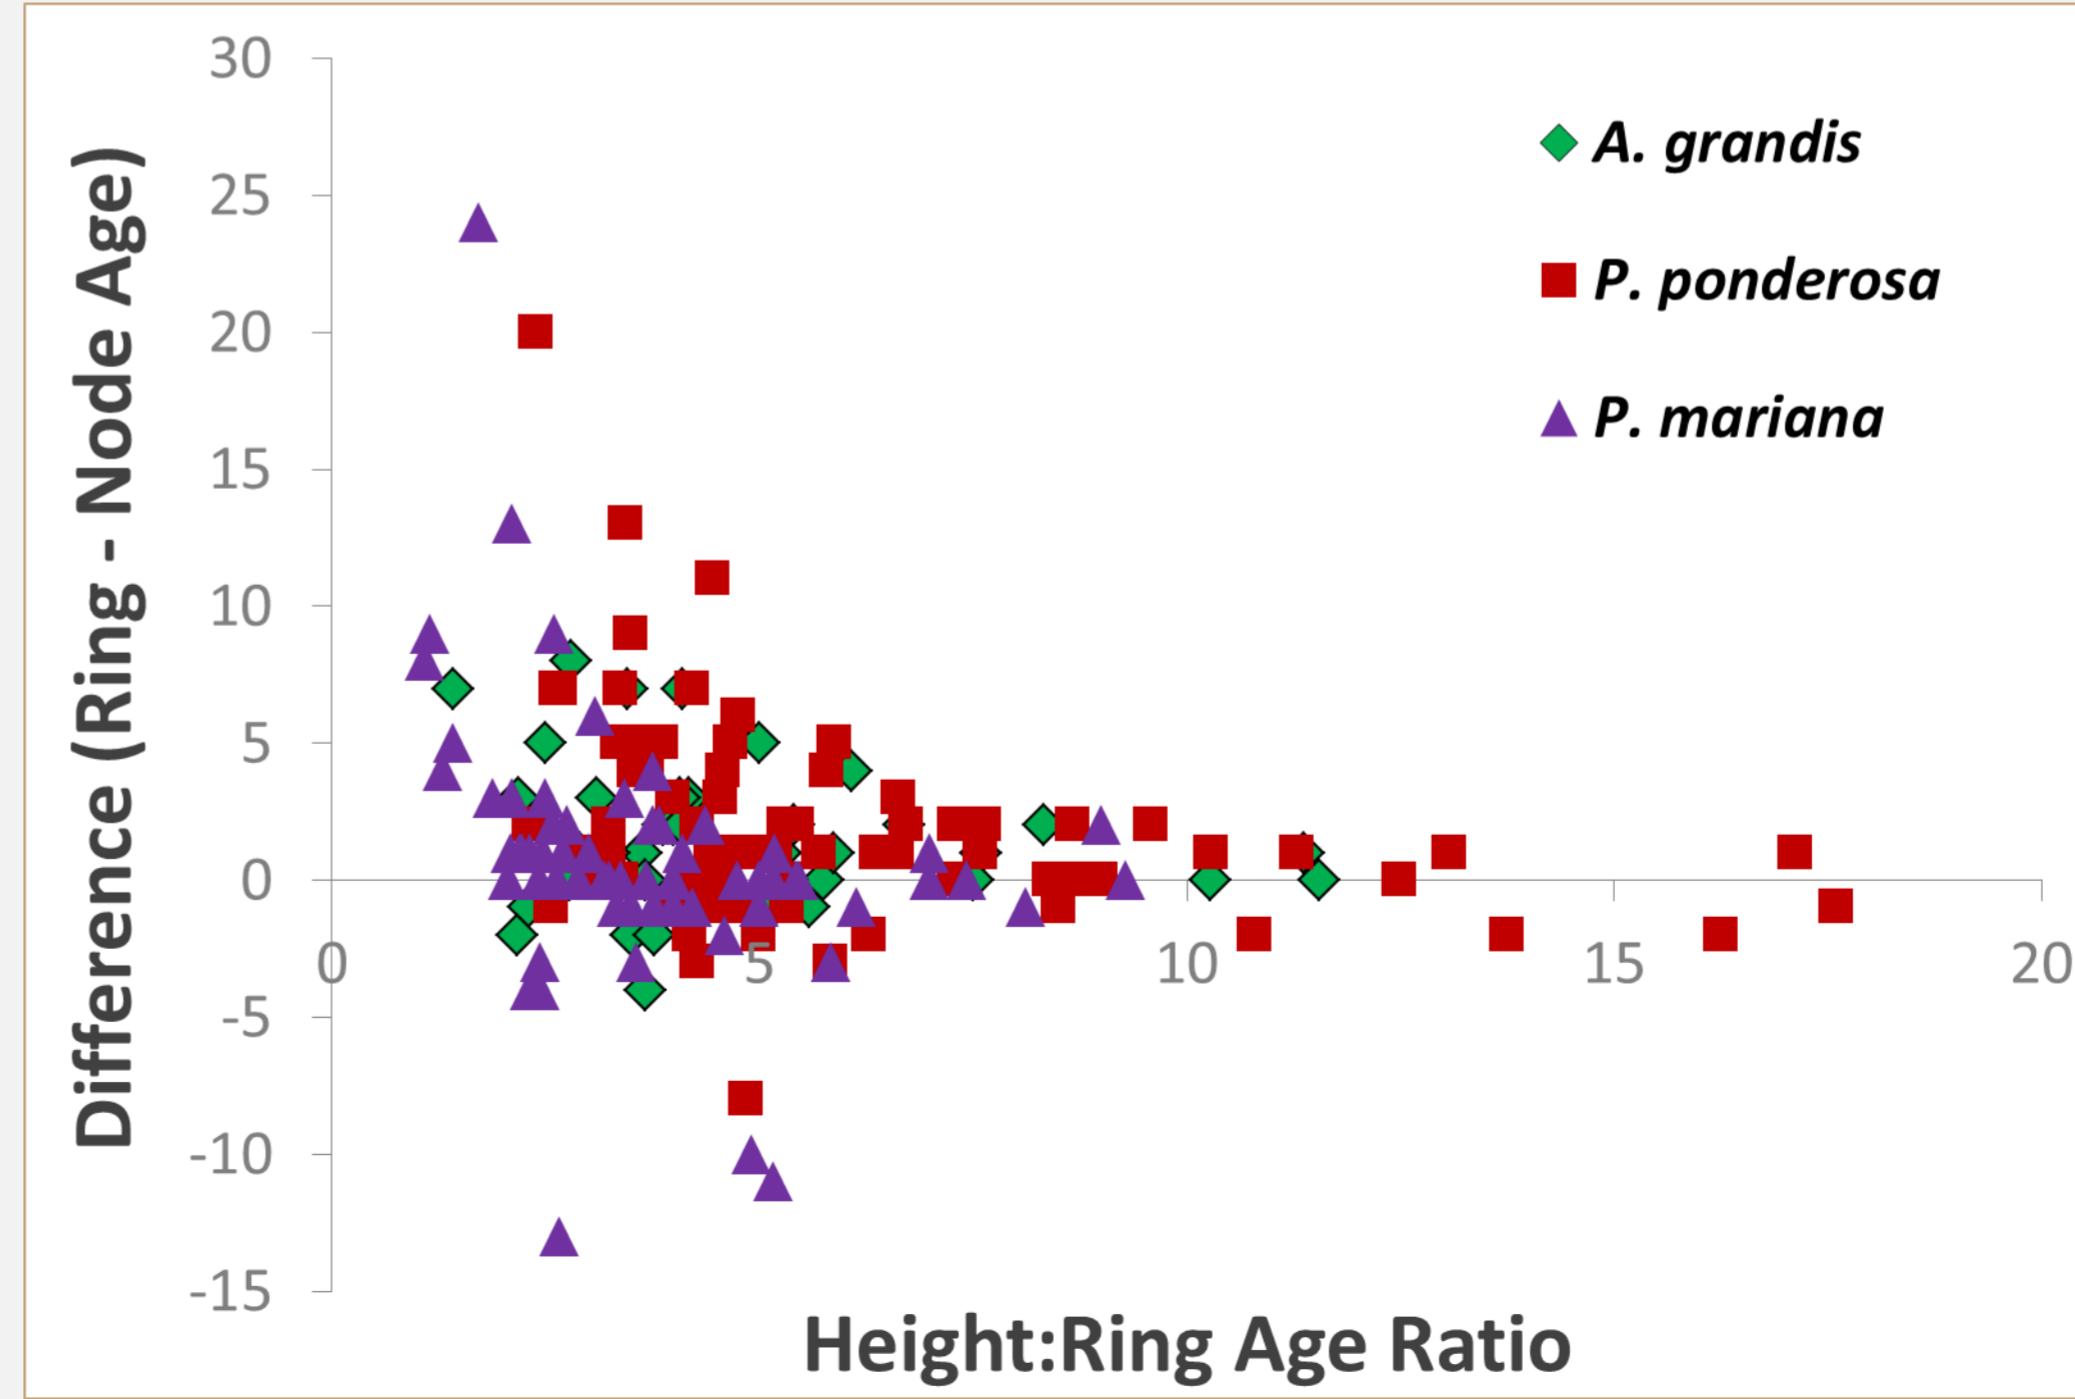

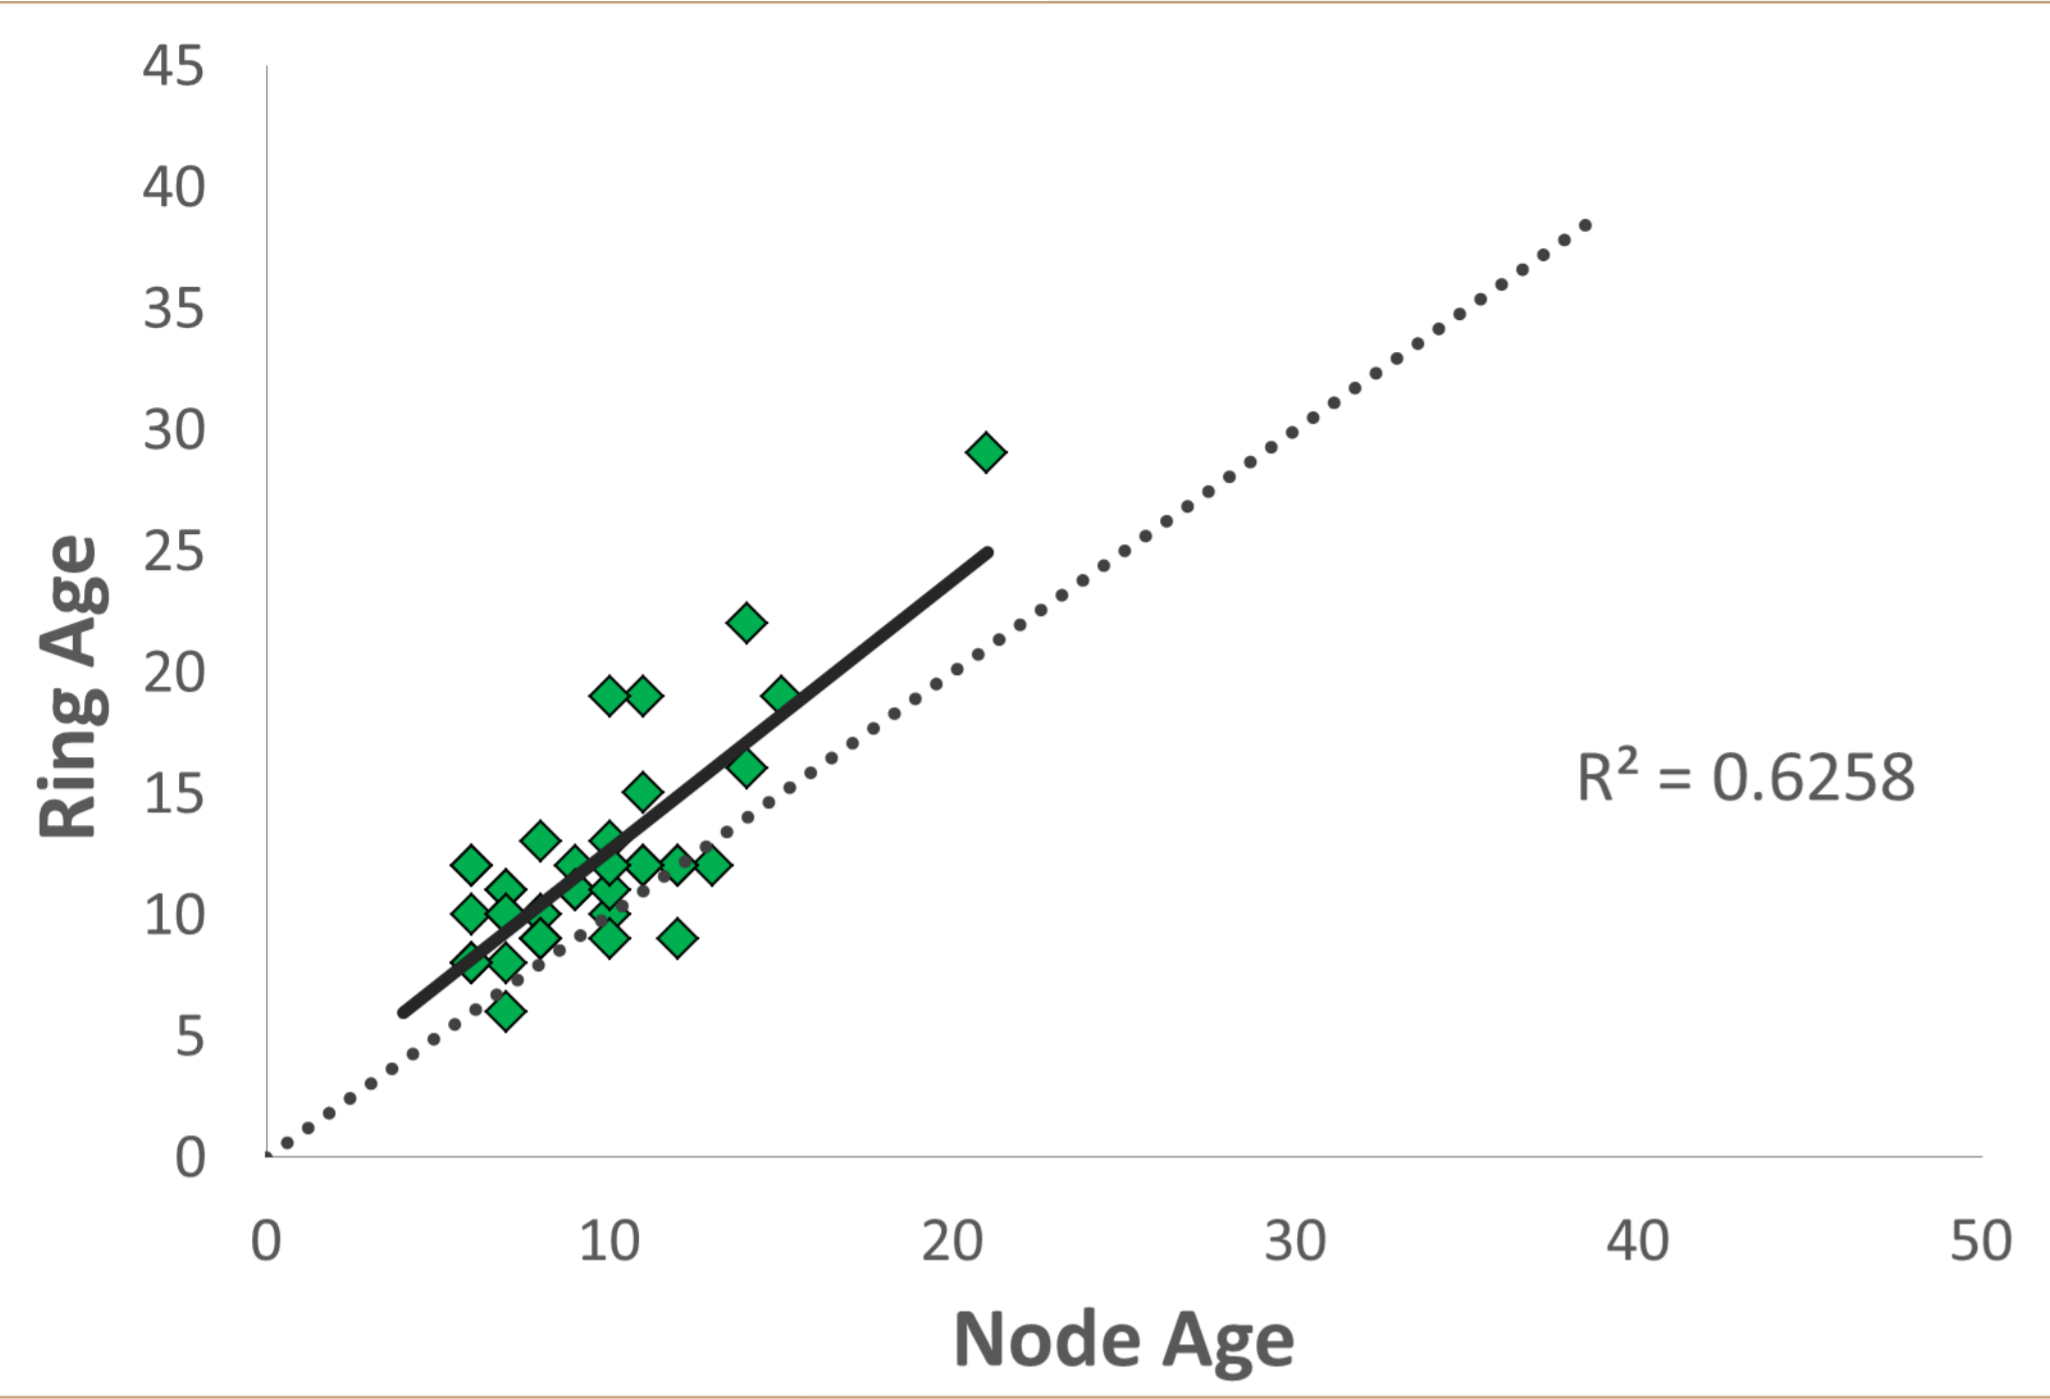

NODE COUNT METHOD

Urza & Sibold 2013

Species	<i>P. ponderosa</i>	<i>P. mariana</i>	<i>A. grandis</i>
RMSE	4.2	0.9	1.3
Mean Error	1.8	0.8	1.6
% Accuracy (0)	17%	27%	18%
% Accuracy +/- 1	49%	56%	45%

WHAT ABOUT OTHER SPECIES?

I Urza & Sibold 2013

- Western larch – least accurate (45%), highest RMSE (2.7)
- Lodgepole pine
- Englemann spruce – most accurate (62%), lowest RMSE (0.98)
- Douglas-fir

NEXT STEP: FIELD GUIDE

- I What should we add? What would be the most helpful?
- I What we're planning to include
 - Accuracy estimates for our species and others from the literature
 - Best practices for using this method

THANKS TO...

- I** Emily Mangini and Jessie Dodge
- I** Funded by JFSP GRIN (17-2-01-11) to Darcy Hammond (student PI) and Eva Strand (PI)
- I** Contact: Darcy Hammond (dhammond@uidaho.edu)
